# SUBRØUT INE FXDAT

#### Subroutine FXDAT

# Purpose

Subroutine FXDAT fixes floating point numbers in the /ARCDAT/ common block, establishes some presets, and prints the data contained in /ARCDAT/.

# Description

In addition to fixing input option flags and curve numbers, FXDAT also establishes presets if certain critical data has not been input. After this, it prints out the arc data.

FXDAT is called from subroutine GEINP for each set of arc data. The single argument, N is the arc number.

# SUBRØUT I NE GET I T

#### Subroutine GETIT

Entry Points. STGIN, PHIN

## Purpose

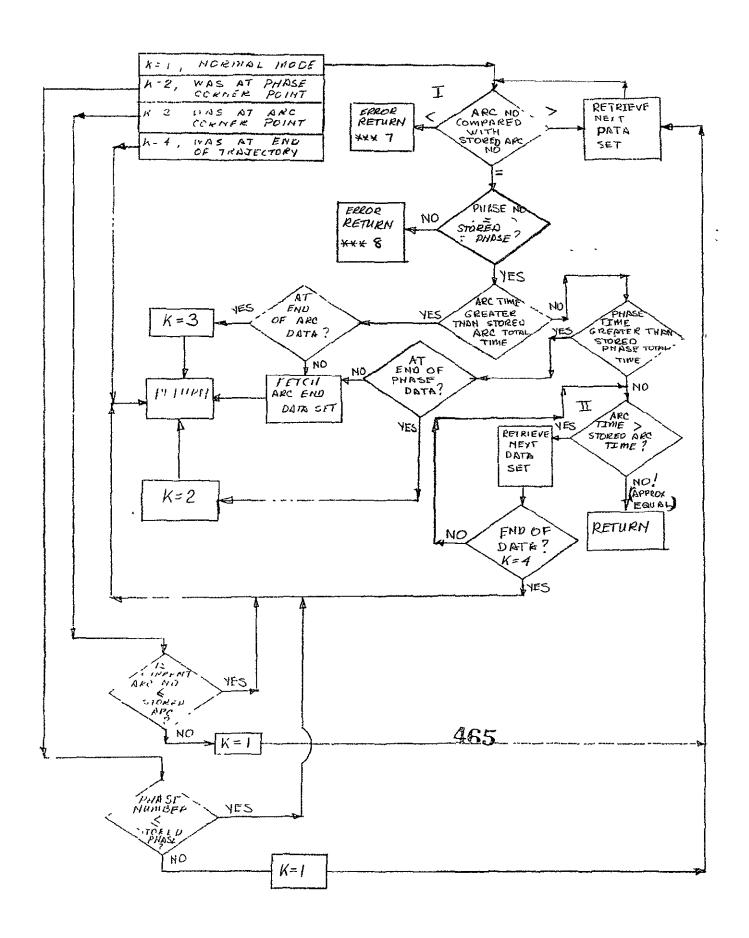

GETIT controls trajectory and adjoint data fetching during forward trial trajectory integration.

### Description

GETIT retrieves data by calling subroutines AGETA and BGET. The main intent of the logic in this routine is to retrieve data from the adjoint and old nominal trajectory at as near the current arc time as possible. (Arc time rather than elapsed time is the independent variable in the program). No data interpolation is done.

Entry points STGIN and PHIN are called by FNTG at the beginning of each arc and phase respectively to locally define total arc and phase durations.

GETIT is called by MODELA.

## SUBRØUT I NE GUI3A

#### Subroutine GUI3A

#### Entry Point, GUID

#### Purpose

GUI3A computes simple nonoptimal control for steepest descent starting solution.

#### Description

The local option flag JGII determines which control calculation is used. This routine is called from MODELA.

| ORTRAN       | MAIH   | CONE  | DESCRIPTION                                        |             | STORA     |      | SUBBOUTINE                                                                                         |                                                              |

## FUNCTION ICOD

#### FUNCTION ICOD

#### Entry IVØD

#### Purpose

The main entry ICOD unpacks the initial condition option code from the packed data boundary condition array word.

The second entry IVOD unpacks the variable code from the word.

#### Description

As described in GEINP, the input boundary conditions are processed and stored on random file 9 record 21. Subroutine SDINP then reads file 9 and employs ICOD and IVOD to get information from the packed words. This information is used to set up internal codes and check input data.

## SUBRØUT I NE I MPUL

#### Subroutine IMPUL

#### Purpose

IMPUL computes specific impulse for rocket propulsion options.

#### Description

This routine has two options, depending on whether JPRO equals 0 or 1. When JPRO = 0, it will compute a corrected ISP if the ISP loss table has been input. When JPR $\emptyset$  = 1, it will always compute a corrected ISP for the dual engine simulation (used with SSSP sizing only).

# SUBROUTINE

#### Subroutine IPR

#### Purpose

IPR is a utility routine used for dumping on to the printer either fixed or tloating point arrays.

#### Printed Output

The output of IPR is a BCD name followed by either a 6 column E format array dump or 10 column fixed point array dump.

## SUBRØUT I NE MØDELA

#### Subroutine MODELA

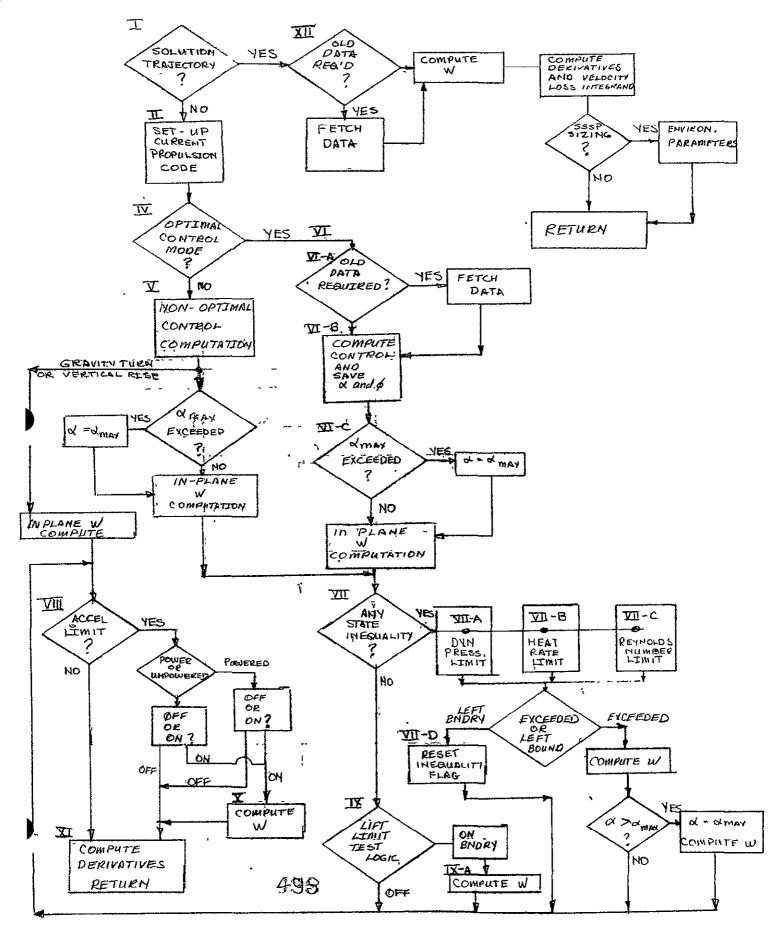

#### Purpose

MODELA governs the computation of the control vector and sets up the derivative calculation during the forward trajectory integration.

#### Description

The way the control vector is calculated depends on options in the program and also on control and state inequality constraints. MODELA does not calculate the control vector (BLGCØN does), but it does test the result of either optimizing or non-optimal control computations to determine if instantaneous constraints have been violated. If constraints are violated, the control mode is instantaneously changed and control is recalculated on the appropriate constraint boundary. After the bounded control is computed, the derivatives are calculated and returned to the calling routine, FNTG.

#### SUBROUTINE MODELA

# SUBRØUTINE MØDELB

#### Subroutine MODELB

## Entry MODEL

#### Purpose

Subroutine MODELB governs the computation of the adjoint coefficients (partial derivatives) during the backward adjoint integration.

### Description

Subroutine MODELB performs a similar function to MODELA with the major exception that control bounding during the adjoint integration is determined by stored values of JP1 and JP3, rather than by inequality testing. MODELB is called from BNTG.

# SUBRØUTINE MØMJ

## FUNCTION MOMJ

## Entry MOMG

## Purpose

MOMJ sets the internal stopping variable flag given the input variable code.

## Description

MOMJ is called from SDINP during the boundary condition scan.

MOMJ

```
FUNCTION MONJ( 1)
  SETS STOPPING VARIABLE FLAS USING INPUT CODE
                       DIMENSION J(36)

DATA (J(N),N=1,36) /2,3,4,5,6,7,8,9,1,99,99,12,13,14,15,16,17,18,

# SUBRØUTINE MPSI

### FUNCTION MPSI

## Purpose

MPSI returns the internal constraint or payoff variable code given the input variable code.

## Description

MPSI is called mainly from SDINP.

MPSI

```
1. C
3. C
4. 5. 6. 7. 8. 9. 10
11 12 13. 14. 15. 16.

# SUBRØUT I NE MTX3A

#### Subroutine MTX3A

### Entry Points

MTX and MTX1

## Purpose

MTX computes the TR vector during closed-loop control. MTX1 computes control and parameter changes during forward trajectory.

### Description

The equations for calculating TR and the control and parameter changes are described in Sections 12.1 and 15.1 of Volume I. MTX3A entry points MTX and MTX1 are called from FNTG, and MODELA respectively.

# SUBRØUT I NE ØUT

#### Subroutine OUT

#### Entry OUTERR

#### Purpose

Subroutine OUT puts data into print array AP in preparation for printing a trajectory block.

### Description

Subroutine OUT controls the computation of auxiliary print quantities (Section 8, Volume I) and checks print options. It loads all desired data into the print array AP and then calls subroutine PRINT which does the formatted printing, heading and labeling. Entry OUTERR is called whenever a control divergence occurs. This entry prints the message:

### :::\*CONTROL DIVERGENCE (SEE NEXT PRINT BLOCK)

And then continues with the remaining code in subroutine OUT to print a standard trajectory block. Subroutine OUT is called from FNTG.

# SUBRØUT I NE PAT63

#### Subroutine PAT63

## Purpose

Subroutine PAT63 computes atmosphere properties and derivatives for the 1963 Patrick Air Force Base atmosphere model.

### Description

The reference for this atmosphere model is noted in Vol I, Section 3.3.2. This model has some programming limitation that should be noted. Above about 360,000 feet, the mathematical representation is very poor; therefore, the properties are automatically fixed at that point and partials are set to zero. Below sea level, a similar procedure is employed in the subroutine.

# SUBRØUT I NE PAYØ2

## Purpose

PAY02 computes the payoff improvement.

## Description

The method of computing the payoff improvement is described in Sections 12.2 and 15.3 of Volume I.

| FORTRAN | HTAM                | CODE | DESCRIPTION                                                                                                             | 5 11    | ) F A G |      | SUBROL                                                                         |                  |                                                              |

# SUBRØUT I NE PDBC

#### Subroutine PDBC

## Purpose

This subroutine computes functions of state and a partial derivative for cut-off, constraint and payoff targets.

## Description

PDBC (and PDBCQL in the quasi-linearization module) contains the equations for all function target conditions available in the trajectory program. These target conditions include the orbital injection parameters, entry range and special targets described in Section 5 of Volume I.

A key feature of the logic in this routine is concerned with the dependance of orbital parameters on one another. This is accommodated by using masking functions to trigger computation of the parameters needed to calculate the desired function.

An example might be when PDBC is called with the variable code argument, KK = 17 meaning eccentricity is to be calculated. The equation sequence necessary for this computation is:

Therefore the masking of variable MM and MASK1, MASK2, and MASK6 is non zero and MM is less than MASK7.

# SUBRØUT I NE PDY3A

#### Subroutine PDY3A

# Entry PDY

#### Purpose

PDY or PDY3A combines and calculates complete partial derivatives of the equations of motion with respect to the state for the adjoint differential equation coefficients. PDY is called from MODEL (MODELB).

# SUBRØUT I NE PRMSET

#### Subroutine PRMSET

### Purpose

PRMSET sets up nominal values of adjustable parameters for next iteration or solution trajectory.

# Description

PRMSET is called from TEST.

# SUBRØUT I NE PRØPB

#### Subroutine PROPB

### Purpose

Subroutine performs arc initialization for adjoint solution.

### Description

PRØPB is called from BNTG.

# SUBRØUT INE PRØP IN

#### Subroutine PROPIN

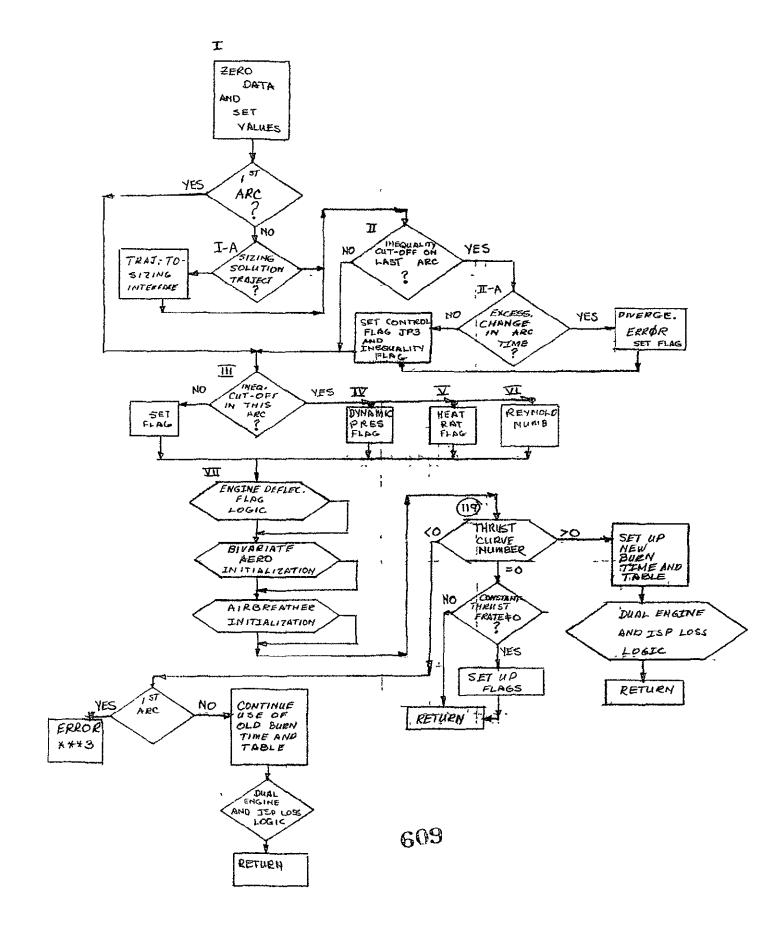

# Purpose

Subroutine PROPIN performs are initialization for the forward trajectory.

# Description

PROPIN is called from FNTG.

# SUBROUTINE PROPIN

# SUBRØUT I NE REU3

#### Subroutine REU3

Entry Points EQIN, SVADYS, SAVVR, SAVDYP, INTBC, BRST, BRIN, MSDISC, CORVAR.

### Purpose

EQIN. Initialize state and control vectors and calculate reference point trigonometric functions.

SVADYS: Save derivatives, y, at arc end points.

SAVVR: Save current state for use in cut-off refinement.

SAVDYP: Save derivatives, y, at phase end point.

INTBC: Evaluate intermediate arc end constraint misses.

BRST: Save state at end of trunk to reinitialize integration for second branch.

BRIN: Evaluate first branch constraint misses and initialize state for beginning of second branch.

MSDISC: Compute mass at beginning of next arc.

CORVAR: Refine mid-integration point state estimate and store.

# SUBRØUT I NE RKTA3A

#### Subroutine RKTA3A

### Entry Point RKUTTA

### Purpose

Subroutine RKTA3A is the utility RUNGE-KUTTA integration routine used for integrating the foward trajectory.

### Description

This Runge-kutta package employs a four-cycle method with two derivatives at the mid-integral and two at the end interval. This routine is called from FNTG.

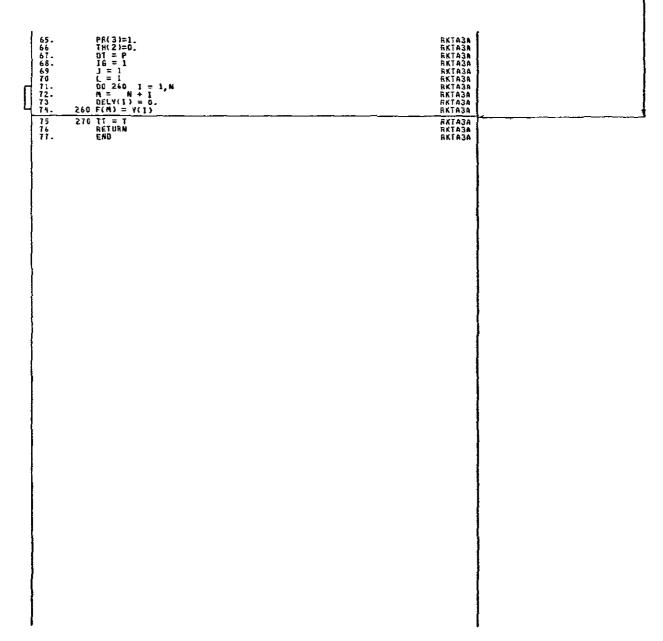

| FORTRAN | MATH   | CODE | DESCRIPTION                                                                                                         |              | <u> 5108</u> |        | SUBROUT1                                                                                                                          |                                                                            |

# SUBRØUT I NE RKTB3A

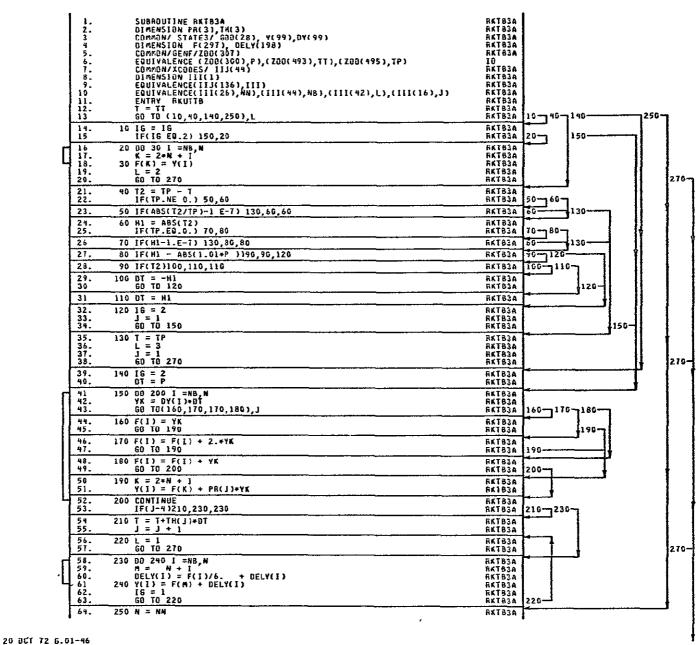

### Subroutine RKTB3A

# Entry Point RKUTTB

## Purpose

Subroutine RKTB3A is the utility RUNGE-KUTTA integration routine used for integrating the adjoint solution.

| FORTRAN | MATH   | CODE | DESCRIPTION                                                                                                          | STORA     |      | SUBBOUTINE USAGE                                                                                                                                     |                                                      |  |

# SUBRØUT I NE SDER3

#### SDER3

### Entry Point SDER

## Purpose

Subroutine SDER3 computes the integrands of ideal velocity and velocity losses during the solution trajectory.

# SUBRØUT I NE SDINP

#### SDINP

### Purpose

SDINP scans and interprets input data.

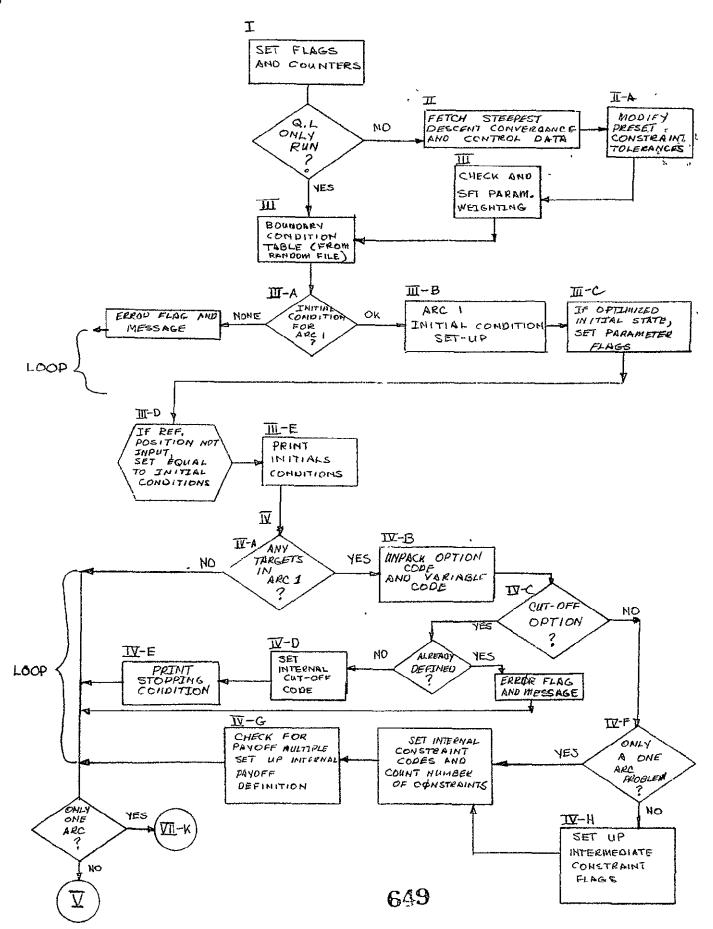

### Description

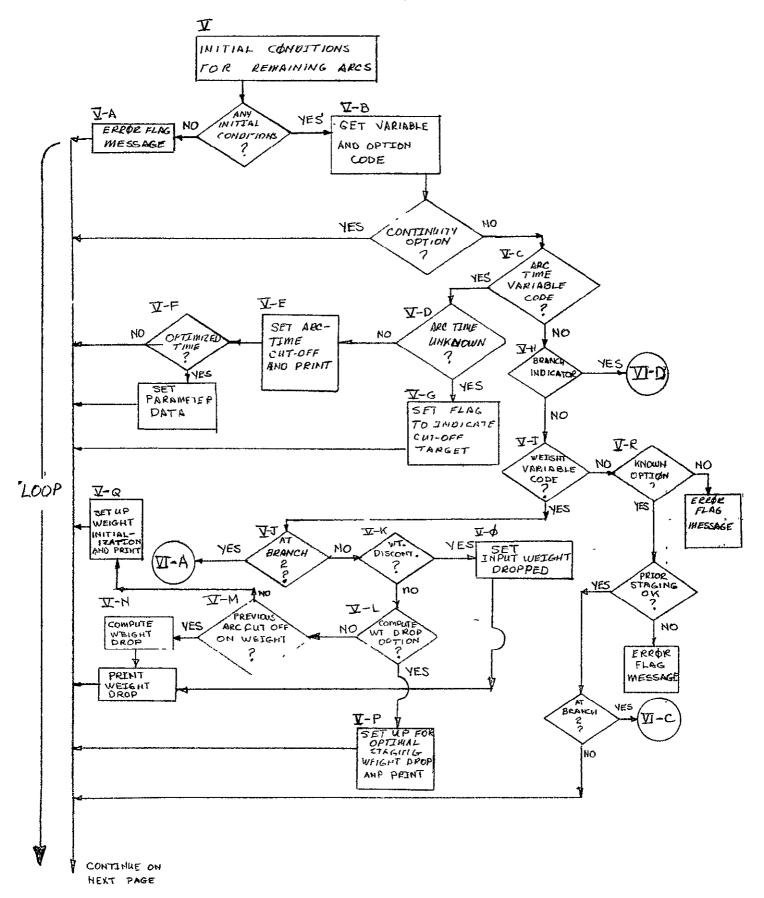

SDINP is an overlay called by the Steepest Descent executive routine, TOPM. The bulk of its coding is related to converting input data into internally used data and flags for the steepest descent module; however, it serves also to check boundary condition data for the quasi-linearization module and print out this data.

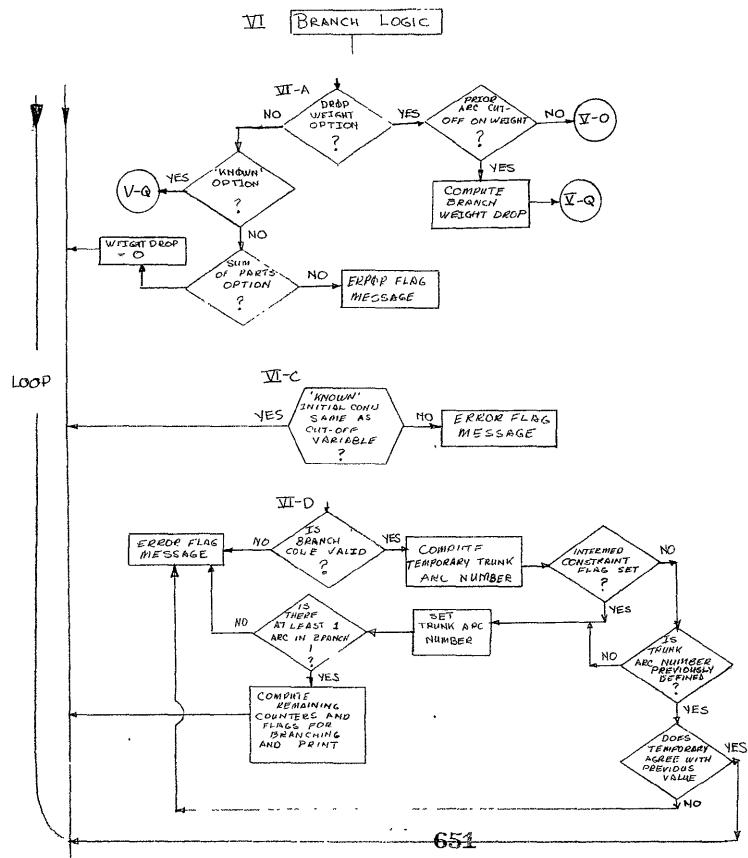

Aside from boundary condition data, SDINP processes the following type of data for the Steepest Descent program.

- 1. Updates of present constraint tolerances and parameter weighting factors
- 2. Tape starting solution initialization.
- 3. Solution control modes
- 4. Starting nominal control modes and tables (no tape solution given)
- 5. Steepest descent convergance data
- 6. Steepest descent storage flags and counters.

# SUBRØUT I NE SØMG

### FUNCTION SOMG

# Entry SPSI

## Purpose

Convert input external units to internal units. SOMG or SPSI is called from SDINP to convert the units of input boundary condition to internal units; i.e., degrees to radians and pounds to slugs-mass.

# SUBRØUT I NE STAU

#### Subroutine STAU

## Entry SINIT, ADJUMP

## Purpose

Subroutine STAU has three entry points. The main entry, STAU, computes the arc time sensitivity. Entry SINIT stores initial state sensitivity in the parameter sensitivity matrix, and prints the entire parameter sensitivity matrix at the completion of the adjoint solution.

Entry ADJUMP computes the adjoint discontinuity at the critical staging time for rubber stage optimization.

## Description

The arc time sensitivity equation is given in equation (12.1-2) of Volume I. The rubber stage adjoint discontinuity is given in Section 13 of Volume I.

# SUBRØUT I NE STPIT

### Subroutine STPIT

### Purpose

Subroutine STPIT is called for fatal errors in steepest descent execution.

## Description

This error routine prints a number message (number comes through argument list) and returns to PADS through a call to entry point SDERR therein.

| FORTHAN | MAIH   | rone    | DESCRIPTION        | STORAL     |     | SUBROUTINE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | USAGE                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# SUBRØUT I NE STP3

#### Subroutine STP3

## Entry Points. PHSTOP, STSTOP, SETFPO

### Purpose

This routine detects whether arc or phase cut-off will be reached in next integration interval on forward trajectory.

### Description

The logic and equations for this routine are described in Section 15.2 of Volume I. This routine as called from FNTG.

# SUBRØUT I NE SUMS

#### FUNCTION SUMS

## Purpose

The purpose of SUMS is to compute the weighted sum of squares of constraint misses for use in determining constraint miss convergence.

## Description

SUMS is called from TEST.

# SUBRØUT I NE SYMVRT

#### Subroutine SYMVRT

#### Purpose

This is a utility symmetric matrix inversion routine.

#### Description

SYMVRT is used to invert the "A" matrix as in equation 12.1-25 of Volume 1. SYMVRT is called from several routines including MTX, PAYO2, and TRAN 3. The method is described in E. Rodewig's Matrix Calculus (North Holland Publishing Co., Amsterdam, 1956), pp. 110-114.

# SUBRØUT I NE TBLK

### Subroutine TBLK

## Purpose

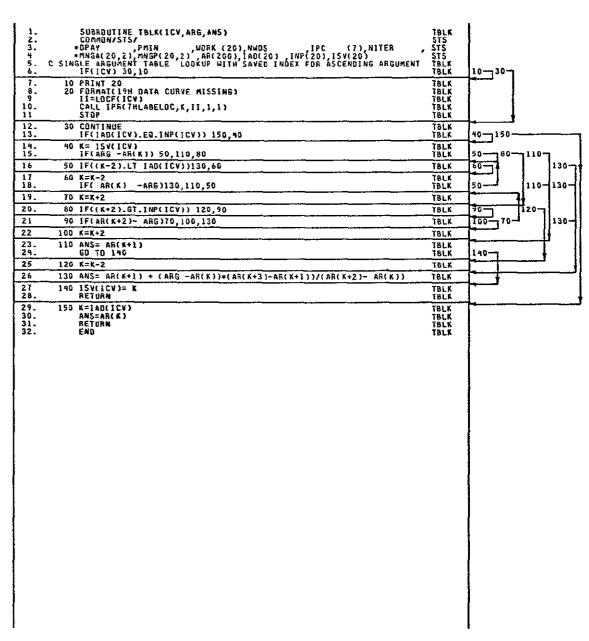

Subroutine TBLK is a single-argument table lookup using linear interpolation.

## Description

This linear interpolation routine is employed for starting-nominal control tables. It saves the index where the last lookup occurred. TBLK is called from GUID3.

# SUBRØUT I NE TEST

#### TEST

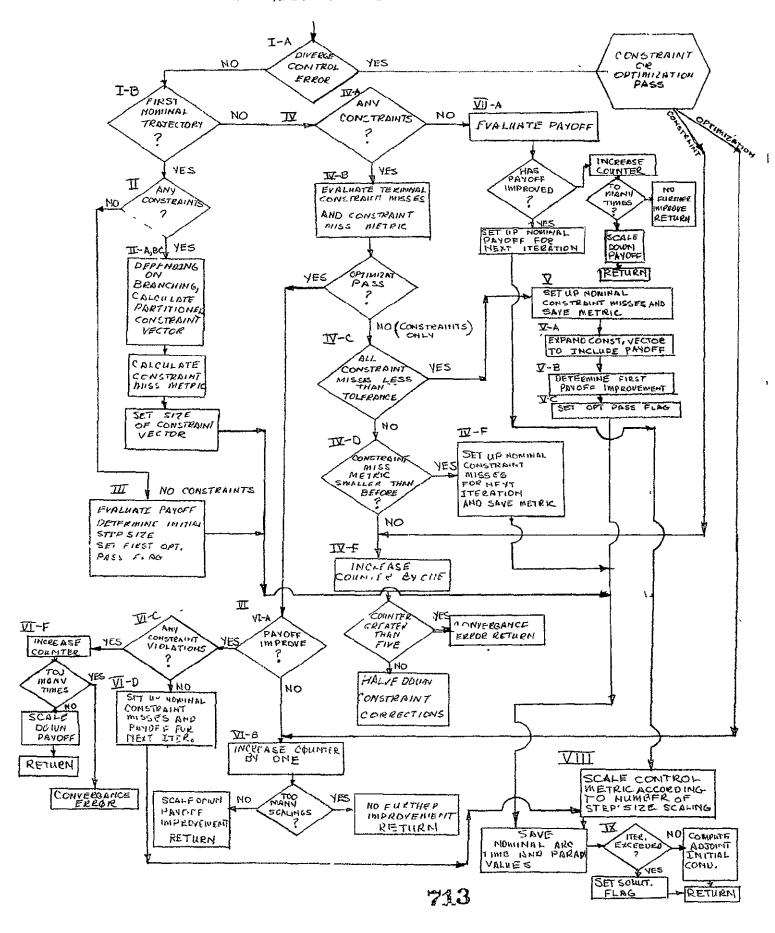

### Purpose

TEST evaluates constraint miss and performance improvement convergance.

### Description

TEST is called by TOPM (steepest descent executive routine) at the completion of each trial trajectory to determine how well solution convergance is going. When difficulties arise, TEST detects them and prints out appropriate messages. Corrective action usually is a successive step size scaling process. When difficulties are not present, TEST calls ADIC to initialize the adjoints for the next adjoint solution-iteration sequence.

#### I TEST FLAGS

FUNCTION TOL PSI

## FUNCTION TØLPSI

### Entry Point SETTOL

## Purpose

 $T\phi$ LPSI supplies a preset constraint tolerance to SDINP during the boundary condition scan.

SETT $\phi$ L is an entry point which permits update of preset constraint tolerances.

# SUBRØUTINE TØL3

### FUNCTION TOL 3

Entry Points. TOLF, TOLPH

### Purpose

Function TOL 3 sets up data for cut-off refinement during the forward trajectory.

### Description

Entry points TOLF and TOLPH are called from FNTG during arc and phase cut-off refinement calculations.

# SUBRØUT I NE TRAN3

### TRAN 3

### Purpose

TRAN3 computes transformed adjoints to serve as approximations for Euler-Lagrange Multipliers. This approximation is used as a starting solution for the quasi-linearization module.

### Description

The equations for TRAN3 are described in Section 14 of Volume I.

## SUBRØUT I NE TRTØSZ

### Subroutine TRTØSZ

### Entry Points. INTER1, ARCEND, TRJEND

### Purpose

Saves trajectory data required for sizing during solution trajectory integration. Entry INTER1 saves initial states. Entry ARCEND saves data at intermediate arc end points. Entry TRJEND saves final weights, impulsive velocity, and velocity losses.

### Description

Entry INTER1 is called from FNTG at the initiation of the forward trajectory. Entry ARCEND is called by subroutine PROPIN. Entry TRJEND is called by FNTG at the terminus of the solution trajectory.

# SUBRØUT I NE VT

#### Subroutine VT

### Entry. VTNOP

### Purpose

Subroutine VT computes the control-dependent terms used in calculating the in-plane control vector. Entry VTNØP computes additional terms needed to calculate the partials of the governing equations with respect to the state.

### Description

Subroutine VT is called by BLGCØN within its iterative scheme which solves for the in-plane control vector. This occurs on both forward trajectories and backward adjoint solutions. Entry VTNØP is called by BLGCØN only on backward adjoint solutions after the governing equations have been solved.

# SUBRØUTINE YREF3

### Subroutine YREF 3

# Entry Points. YREF, PSD

### Purpose

Subroutine YREF3 (ENTRY YREF) refines cut-off time and state using third-order interpolation.

Entry PSD saves derivative at estimated cut-off point for use in entry YREF.

## Description

The equations and logic for the subroutine are described in Section 15.1 of Volume I. This routine is called for non-time arc cut-offs from FNTG.

# is made in filling your order, if the item was received replacement will be provided if an error NTIS does not permit return of items for credit or in damaged condition, or if the item is defective.

Reproduced by NTIS
National Technical Information Service
U.S. Department of Commerce
Springfield, VA 22161

This report was printed specifically for your order from our collection of more than 2 million technical reports.

For economy and efficiency, NTIS does not maintain stock of its vast collection of technical reports. Rather, most documents are printed for each order. Your copy is the best possible reproduction available from our master archive. If you have any questions concerning this document or any order you placed with NTIS, please call our Customer Services Department at (703)487-4660.

Always think of NTIS when you want:

- Access to the technical, scientific, and engineering results generated by the ongoing multibillion dollar R&D program of the U.S. Government.
- R&D results from Japan, West Germany, Great Britain, and some 20 other countries, most of it reported in English.

NTIS also operates two centers that can provide you with valuable information:

- The Federal Computer Products Center offers software and datafiles produced by Federal agencies.
- The Center for the Utilization of Federal Technology gives you access to the best of Federal technologies and laboratory resources.

For more information about NTIS, send for our FREE *NTIS Products* and *Services Catalog* which describes how you can access this U.S. and foreign Government technology. Call (703)487-4650 or send this sheet to NTIS, U.S. Department of Commerce, Springfield, VA 22161. Ask for catalog, PR-827.
